

SolDecode

G o^ý0n0ª0ü0×0ó0½0ü0¹ S D K0g S o l a n a0nu T}Nä0'a Ts0n0B0<0¢0¯0·0ç0

The Problem & Our Solution

Every Solana team rewrites fragile instruction parsers from scratch. SolDecode gives developers a shared, tested decoding layer instead.

- Raw Solana instructions and logs are hard to interpret without custom, brittle parsing code
- Non-web3 engineers struggle to build dApps, explorers, and wallets without clear transaction semantics
- SolDecode is an open-source Go SDK that decodes instructions into structured, semantic actions
- Exposed as both a Go package and a REST/gRPC API, usable by Go and non-Go teams alike
- Pluggable decoders cover System, Token, Jupiter, Orca, Marinade, and more

How It Works

A developer sends a transaction signature or wallet address; SolDecode fetches, decodes, and returns structured JSON events.

- User flow: submit a tx signature or wallet address via REST API or CLI
- SolDecode fetches raw instructions and logs through the Solana RPC API
- A decoder registry matches each instruction to its program-specific decoder using Anchor IDL/Borsh
- Output is structured JSON describing the semantic action, e.g. a swap or transfer
- On-chain: no new programs are deployed, SolDecode only reads and interprets existing activity

Built with

Solana, Go, Solana RPC API, Anchor IDL/Borsh decoding, gRPC, REST, Docker

Why Now & What's Next

More non-crypto developers are entering Solana and need shared decoding infrastructure instead of rebuilding brittle parsers.

Category

Infrastructure

- Solana adoption is growing beyond native crypto teams, raising demand for simpler tooling
- Shared decoding infra is becoming the 'web2 ORM for blockchain' layer Solana currently lacks
- Next: grow decoder coverage through community contributions and a program registry
- Next: publish as a Go module plus a hosted API with usage-based pricing
- Next: partner with wallets and explorers to adopt SolDecode as their parsing backend
